(57) **ABSTRACT**

The present invention concerns methods and kits for diagnos-
 ing a disease condition characterized by non-physiological
 levels of hepcidin protein, including prohepcidin and frag-
 ments thereof, comprising obtaining a tissue or fluid sample
 from a subject; contacting the sample with an antibody or
 fragment thereof that specifically binds to a polypeptide cor-
 responding to the amino acid sequence between and includ-
 ing amino acids 25 and 49 of a hepcidin precursor protein, and
 quantifying the hepcidin precursor level using an assay based
 on binding of the antibody and the polypeptide; wherein the
 non-physiological level of prohepcidin is indicative of the
 disease condition. The present invention also concerns diag-
 nostic methods and kits for applications in genetic techno-
 logical approaches, such as for overexpressing or downregu-
 lating hepcidin.

DIAGNOSTIC METHOD FOR DISEASES BY SCREENING FOR HEPCIDIN IN HUMAN OR ANIMAL TISSUES, BLOOD OR BODY FLUIDS AND THERAPEUTIC USES THEREFOR

CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a Continuation of application Ser. No. 10/299,486 filed Nov. 19, 2002, now U.S. Pat. No. 7,411,048.

BACKGROUND ART

Iron is an essential trace element that is required indispensable for DNA synthesis and a broad range of metabolic processes. However, disturbances of iron metabolism have been implicated in a number of significant mammalian diseases, including, but not limited to iron deficiency anemia, hemosiderosis or the iron overload disease hemochromatosis (Andrews, N. C. (2000) *Annu. Rev. Genomics Hum. Genet.* 1, 75-98; Philpott, C. C. (2002) *Hepatology* 35, 993-1001; Beutler et al., (2001) *Drug-Metab. Dispos.* 29, 495-499). Excess iron accumulation has an adverse effect, as exemplified by patients with hereditary hemochromatosis, some of whom die at an early age from cirrhosis of the liver, diabetes, and cardiac failure. Beutler et al., (2001) *Drug-Metab. Dispos.* 29, 495-499. Iron content in mammals is regulated by controlling absorption predominantly in the duodenum and upper jejunum, and is the only mechanism by which iron stores are physiologically controlled (Philpott, C. C. (2002) *Hepatology* 35, 993-1001). Following absorption, iron is bound to circulating transferrin and delivered to tissues throughout the body. The liver is the major site of iron storage. There, transferrin-bound iron is taken into the hepatocytes by receptor-mediated endocytosis via the classical transferrin receptor (TfR1) (Collawn et al., (1990) *Cell* 63, 1061-1072) and presumably in greater amounts via the recently identified homologous transferrin receptor 2 (TfR2) (Kawabata et al., (1999) *J. Biol. Chem.* 274, 20826-20832). The extracellular domain of this protein is 45% identical to the corresponding portion of TfR1 (Id.). TfR2 can also bind diferric transferrin and facilitate the uptake of iron. Mutations in TfR2 have been associated with certain forms of hemochromatosis demonstrating the important role for TfR2 in iron homeostasis (Philpott, C. C. (2002) *Hepatology* 35, 993-1001; Camasehella et al., (2000) *Nat. Genet.* 25, 14-15; Fleming et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 10653-10658). TfR2 is predominantly expressed in the liver (Fleming et al., (2000) *Proc. Natl. Acad. Sci. USA* 97, 2214-2219; Subramaniam et al., (2002) *Cell Biochem. Biophys.* 36, 235-239), however, the exact cellular localization is still unknown.

A feedback mechanism exists that enhances iron absorption in individuals who are iron deficient, and reduces iron absorption in subjects with iron overload (Andrews, N. C. (2000) *Annu. Rev. Genomics Hum. Genet.* 1, 75-98; Philpott, C. C. (2002) *Hepatology* 35, 993-1001; Beutler et al., (2001) *Drug-Metab. Dispos.* 29, 495-499). Nonetheless, the molecular mechanism by which the intestine responds to alterations in body iron requirements remains poorly understood. In this context, hepcidin, a recently identified mammalian polypeptide (Krause et al., (2000) *FEBS Lett.* 480, 147-150; Park et al., (2001) *J. Biol. Chem.* 276, 7806-7810), is predicted as a key signaling component regulating iron homeostasis (Philpott, C. C. (2002) *Hepatology* 35, 993-1001; Nicolas et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 4396-4601). Hepcidin was initially isolated as a 25 amino acid (aa) polypeptide

2

in human plasma and urine exhibiting antimicrobial activity (Krause et al., (2000) *FEBS Lett.* 480, 147-150; Park et al., (2001) *J. Biol. Chem.* 276, 7806-7810). A hepcidin cDNA encoding an 83 aa precursor in mice and an 84 aa precursor in rat and man, including a putative 24 aa signal peptide, were subsequently identified searching for liver specific genes that were regulated by iron (Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819).

Since the discovery that hepcidin expression is abolished in mice exhibiting iron-overload due to the targeted disruption of upstream stimulatory factor 2 (Usf2) gene resembling the same phenotype as found in Nicolas, O., Bennoun, M., Devaux, I., Beaumont, C., Grandchamp, B., Kahn, A. & Vaulont, S. (2001) *Proc. Natl. Acad. Sci. USA* 98, 8780-8785, it has become evident that this peptide plays a pivotal role in iron metabolism. In contrast, overexpression of hepcidin was shown to result in severe iron deficiency anemia in transgenic mice (Nicolas et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 4396-4601), indicating that hepcidin is a central regulator of iron homeostasis. However, the mechanism by which hepcidin balances the body iron stores or adjusts the dietary iron absorption still remains to be identified. In this respect, the cellular and subcellular localization of this peptide is of decisive importance in the search for the signaling route. Although Northern blot analysis of human and mouse hepcidin mRNA levels in various organs revealed that hepcidin is predominantly expressed in liver, no data exist on the cellular source of this polypeptide (Krause et al., (2000) *FEBS Lett.* 480, 147-150; Park et al., (2001) *J. Biol. Chem.* 276, 7806-7810; Nicolas et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 4396-4601).

SUMMARY OF THE INVENTION

The present invention concerns hepcidin regulation of iron uptake by mammalian cells and the use of hepcidin and/or hepcidin specific antibodies in the diagnosis of diseases involving disturbances of iron metabolism. The diagnostic detection kits of the present invention can be particularly useful in screening the overall population of either humans or animals and identifying those subjects who have these diseases.

One aspect of the invention is a method for diagnosing a disease condition characterized by non-physiological levels of hepcidin, comprising obtaining a tissue or fluid sample from a subject; contacting the sample with an antibody or fragment thereof that specifically binds to a polypeptide from the mid-portion (amino acids 20 to 50 of SEQ ID NO: 2) or C-terminus of hepcidin (amino acids 65 to 84 of SEQ ID NO: 2), and quantifying the hepcidin level using an assay based on binding of the antibody and the polypeptide; wherein the non-physiological level of hepcidin is indicative of the disease condition. In one aspect of the present invention, sensitive diagnostic methods and kits were established enabling the detection of pro-hepcidin in human plasma. The invention opens a broad range of therapeutic perspectives, where a hepcidin antibody and diagnostic methods and kits can be used for the determination of hepcidin as a parameter for the progress of the diseases mentioned above during and after therapy.

One embodiment of the invention concerns the generation and purification of a hepcidin protein and fragments thereof. Another embodiment of the invention concerns hepcidin specific antibodies, or fragments or variants thereof that, in turn, can be used in immunoassays to detect a hepcidin protein in suspected humans or animals.

In another aspect of the invention, the hepcidin diagnostic methods and kits can be used in genetic technological approaches, such as for overexpressing or downregulating hepcidin.

In still another aspect of the invention, hepcidin can be used in therapeutic treatment of the diseases described herein, by treating subjects with hepcidin, and agonists or antagonists of hepcidin. Iron uptake in cells could be modulated by varying the concentration of hepcidin, inhibiting hepcidin binding to iron or to the Tfr2 receptor. Accordingly, hepcidin, and agonists or antagonists of hepcidin may be useful in the treatment of conditions where there is a disturbance in iron metabolism. For example, such substances may be useful in the treatment of such aforementioned diseases.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1. (A, B) RT-PCR analysis of human liver (lanes 2 and 3) and HepG2 cells (lanes 4 and 5) showing gene expression of hepcidin (A) and Tfr2 (B) with amplification products of correct molecular size. A bp DNA ladder is indicated (lanes 1 and 7). Lanes 6 show a negative control.

(C-E) Western blot analyses of hepcidin in extracts of guinea pig (lanes 1) and human liver (lanes 2) as well as in HepG2 cells (lanes 3) and guinea pig skeletal muscle (lanes 4, control) with antibodies EG(1)-HepN[®], EG(2)-HepN (D) and EG(1)-HepC (E). Note the immunoreactive bands at 10 and 20 kDa obtained with all antibodies recognizing different epitopes in a hepcidin precursor. (F) Western blot analysis of Tfr2 in extracts of mouse liver (1), human liver (2), HepG2 cells (3) and mouse heart (4) (control).

FIG. 2. Cellular localization of hepcidin in guinea pig (A-F) and human (G-I) liver. The paraffin sections immunostained with the region-specific antibodies EG(1)-HepN (A, D, G), EG(2)-HepN (B, E, H) and EG(1)-HepC (C, F, I) show a distinct immunoreactivity at the basolateral membrane domain of hepatocytes (arrows). (Magnification: A-C, $\times 180$; D-I, $\times 540$).

FIG. 3. Immunohistochemical sections (A, antibody EG(1)-HepN; B, antibody EG(2)-HepN; C, antibody EG(1)-HepC showing the clear zonation of hepcidin within the hepatic lobules with decreasing immunoreactivity from periportal zones (stars) towards the central veins (arrowheads). Note that no immunoreactivity is found in hepatocytes around the central veins. (The arrow in B indicates a portal triad.) (A-C, $\times 180$).

FIG. 4. Immunohistochemical localization of Tfr2 in mouse (A-C) and human liver (D) using the antibody BT-TFR21-S. Note that immunoreactivity is exclusively confined to the basolateral membrane (arrows) of hepatocytes; no immunoreactivity is found around the central veins (stars in A and C). A slight zonation for Tfr2 is seen in A with decreasing immunoreactivity toward the central vein (A, $\times 180$; B, C, $\times 360$; D, $\times 540$).

FIG. 5. Detection of hepcidin (A-C) and Tfr2 (D) in HepG2 cells by immunofluorescence microscopy using the antibodies EG(1)-HepN (A), EG(2)-HepN (B), EG(1)-HepC (C), and BT-TFR21-S (D) (Scale bar 8 mm).

FIG. 6. ELISA for circulating human hepcidin. A representative standard curve with concentrations of hepcidin-(28-47) (SEQ ID NO: 3) in ng/ml and the extinction of the ELISA solution at 450 nm wavelength are shown. Note the high resolving power in the range of 1 to 400 ng/ml hepcidin-(28-47).

FIG. 7 shows the complete nucleotide (SEQ ID NO: 1) and amino acid sequences (SEQ ID NO: 2) of one form of hepcidin reproduced from GenBank database accession nos. NM021175 and AAH20612, respectively.

DETAILED DESCRIPTION OF THE INVENTION

The present invention describes that hepcidin regulates iron uptake by mammalian cells and nonphysiological express of hepcidin results in disease involved distribution of iron metabolism. The physiological concentration of hepcidin is in the range of 200-260 ng/mL. Nonphysiological concentrations are below or over this range. Nonphysiological amounts of hepcidin protein or fragment thereof are associated with disturbances of iron metabolism, resulting in iron deficiency or overload, such as iron deficiency anemia; genetic and nongenetic iron overload diseases, such as hemosiderosis and hemochromatosis or secondary hemochromatosis, aceruloplasminemia, hypotransferrinemia, atransferrinemia; iron overload diseases of undetermined origin, for instance in the case of diseases of the biliary system, liver diseases, especially alcoholic liver diseases, nonalcoholic steatohepatitis, and chronic hepatitis B and C infections; diseases of utilization of iron, such as sideroblastic anemia, thalassemia; hematologic diseases, such as leukemia, polycythemia, macrocytic, microcytic or normocytic anemia, anemia with reticulocytosis, hemolytic anemia; disturbances of the reticuloendothelial system due to infections and diseases; inflammations and infections, including sepsis; immunologic diseases and tumors, such as carcinoma, sarcoma, lymphoma, that result in non-physiologic hepcidin concentrations; neurodegenerative diseases, such as Alzheimer's disease and Wilson's disease. The clinical consequences of iron overload include cirrhosis of the liver and hepatocellular cancer, diabetes, heart failure, arthritis, and hypogonadism. Zhou et al., Proc. Natl. Acad. Sci., 95, 2492-2497 (1998). This discovery has permitted the development of assays for a hepcidin protein and fragments thereof and their subsequent purification with retention of their native configuration and physiological activity. The invention is based, in part, on the discovery that in patients suffering from certain disorders a hepcidin protein is present in tissue, blood and body fluid of a human or animal.

This invention provides the first demonstration that a hepcidin protein in subjects of these disorders are present in human or animal tissue, blood and body fluids in concentrations greatly exceeding that found in normal humans or animals that are not subjects of these disorders. This is achieved by examining a sample of tissue, blood or body fluid from a patient, and detecting the presence and quantity of hepcidin protein. The detection and quantitative measurement of any hepcidin protein or fragment thereof in tissue, blood or body fluids in accordance with this invention is useful in confirming a clinical diagnosis of the diseases described herein, in affected patients and in following the course of the disease. The invention is also useful in monitoring the disease during and subsequent to a period of treatment with agents that are being tested for their ability to stabilize, decrease or prevent the occurrence of such diseases.

For purposes of description only, the invention will be described in terms of: (a) generating a hepcidin protein or fragments thereof; (b) generating antibodies that specifically bind a hepcidin protein; (c) diagnostic assays and kits for diagnosing subtyping or monitoring the diseases described herein; (d) methods for over expressing and down regulating hepcidin; and (e) therapeutic treatment of the diseases described herein.

Production of a Hecpidin Protein

Isolating a Hecpidin Protein from Blood and Body Fluids

For purposes of the present invention the term hecpidin protein is defined as any mammalian hecpidin polypeptide sharing about 80 percent amino acid sequence identity with the predicted amino acid sequence published by Pigeon and co-workers ((2001) *J. Biol. Chem.* 276, 7811-7819). The hecpidin proteins provided herein also include proteins characterized by amino acid sequences similar to those of purified hecpidin proteins but into which modification are naturally provided or deliberately engineered. For example, modifications in a hecpidin peptide or DNA sequences can be made by those skilled in the art using known techniques. Modifications of interest in a hecpidin protein sequences may include the alteration, substitution, replacement, insertion or deletion of a selected amino acid residue in the coding sequence. For example, one or more of the cysteine residues may be deleted or replaced with another amino acid to alter the conformation of the molecule. Techniques for such alteration, substitution, replacement, insertion or deletion are well known to those skilled in the art (see, e.g., U.S. Pat. No. 4,518,584). Preferably, such alteration, substitution, replacement, insertion or deletion retains the desired activity of the protein. Regions of a hecpidin protein that are important for the protein function can be determined by various methods known in the art including the alanine-scanning method which involved systematic substitution of single or strings of amino acids with alanine, followed by testing the resulting alanine-containing variant for biological activity. This type of analysis determines the importance of the substituted amino acid(s) in biological activity.

Production of a hecpidin protein may be accomplished by isolating a hecpidin protein from the tissue, blood or body fluids of humans or animals suffering from hemochromatosis, iron deficiency anemia, hemosiderosis, liver cirrhosis and other such diseases described herein, using standard techniques known by those of skill in the art. Such techniques included in the invention also relate to methods for producing a hecpidin protein comprising growing a culture of host cells in a suitable culture medium, and purifying a hecpidin protein from the cells or the culture in which the cells are grown.

A variety of methodologies known in the art can be utilized to obtain any one of the isolated hecpidin proteins of the present invention. For example, a hecpidin protein can also be produced by chemical synthesis of the amino acid sequence of a hecpidin protein (Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819), as predicted from the cloning and sequencing of a cDNA coding for a hecpidin protein. This hecpidin protein sequence information may be utilized to predict the appropriate amino sequence of a fragment of a hecpidin protein to be chemically synthesized using standard peptide synthesis methods known in the art. These methods include a solid-phase method devised by R. Bruce Merrifield, (Erickson and Merrifield, "Solid-Phase Peptide Synthesis", in *The Proteins*, Volume 2, H. Neurath & R. Hill (Eds.) Academic Press, Inc., New York pp. 255-257; Merrifield, (1986) "Solid phase synthesis", *Science*, 242:341-347). In the solid-phase method, amino acids are added stepwise to a growing peptide chain that is linked to an insoluble matrix, such as polystyrene beads. A major advantage of this method is that the desired product at each stage is bound to beads that can be rapidly filtered and washed and thus the need to purify intermediates is obviated. All of the reactions are carried out in a single vessel, which eliminates losses due to repeated transfers of products. This solid phase method of chemical peptide synthesis can readily be automated making it feasible to routinely synthesize peptides containing about 50 residues in good

yield and purity (Stewart and Young, (1984) *Solid Phase Peptide Synthesis*, 2nd ed., Pierce Chemical Co.; Tam et al., (1983) *J. Am. Chem. Soc.*, 105:6442). For example, a hecpidin protein fragment corresponding to amino acid residues 1 to 50, or 34 to 84 as depicted in FIG. 7 could be synthesized. At the simplest level, commercially available peptide synthesizers are particularly useful in producing small peptides and fragments of a hecpidin protein. Fragments are useful, for example, in generating antibodies against the native hecpidin protein.

One skilled in the art can readily follow known methods for isolating proteins in order to obtain one of the isolated hecpidin proteins/peptides of the present invention. These include, but are not limited to, immunochromatography, HPLC, size-exclusion chromatography, ion-exchange chromatography, and immuno-affinity chromatography. See, e.g., Scopes, *Protein Purification: Principles and Practice*, Springer-Verlag (1994); Sambrook, et al., in *Molecular Cloning: A Laboratory Manual*; Ausubel et al., *Current Protocols in Molecular Biology*.

Finally, one or more reverse-phase high performance liquid chromatography (RP-HPLC) steps employing hydrophobic RP-HPLC media, e.g., silica gel having pendant methyl or other aliphatic groups, can be employed to further purify a hecpidin protein. Some or all of the foregoing purification steps, in various combinations, can also be employed to provide a substantially homogeneous isolated recombinant hecpidin protein. A hecpidin protein thus purified is substantially free of other mammalian proteins and is defined in accordance with the present invention as an isolated protein.

The sequence of a hecpidin protein may be identified using the Edman degradation method of protein sequencing. This method sequentially removes one amino acid residue at a time from the amino terminal end of a peptide for subsequent sequence identification by chromatographic procedures. See for example, the techniques described in Konigsberg and Steinman, (1977) *Strategy and Methods of Sequence Analysis*, in Neurath and Hill (eds.), *The Proteins* (3rd ed.) Vol. 3, pp. 1-178, Academic Press. In addition, sequence analysis of a hecpidin protein may be accelerated by using an automated liquid phase amino acid sequencer following described techniques (Hewick et al., (1981) *J. Biol. Chem.*, 256:7990-7997; Stein and Undefried, (1984) *Analy. Chem.*, 136:7-23), thereby allowing for the analysis of picomolar quantities of a hecpidin protein.

The purified hecpidin protein can be used in in vitro binding assays that are well known in the art to identify molecules that bind to a hecpidin protein. These molecules include but are not limited to, for e.g., small molecules, molecules from combinatorial libraries, antibodies or other proteins. The molecules identified in the binding assay are then tested for agonist or antagonist activity in in vivo tissue culture or animal models that are well known in the art. In brief, the molecules are titrated into a plurality of cell cultures or animals and then tested for either cell/animal death or prolonged survival of the animal/cells.

In addition, the binding molecules may be complexed with toxins, e.g., ricin or cholera, or with other compounds that are toxic to cells. The toxin-binding molecule complex is then targeted to a tumor or other cell by the specificity of the binding molecule for a hecpidin protein.

Cloning and Expression of Recombinant Hecpidin Protein

In other embodiments, production of a hecpidin protein can be achieved by recombinant DNA technology. For example, appropriate hecpidin nucleotide coding sequences may be synthesized, cloned and expressed in appropriate host cells.

Since the DNA sequence coding for a hepcidin protein is known (Pigeon et al., (2001) J. Biol. Chem. 276, 7811-7819), DNA probes may be synthesized by standard methods known in the art to screen cDNA libraries prepared from liver tissue from human or animal subjects suffering from hemochromatosis, iron deficiency anemia, hemosiderosis, liver cirrhosis and other diseases described herein, for specific hepcidin protein cDNA's. These DNA probes can further be used to isolate the entire family of hepcidin protein genes from these cDNA libraries using methods that are well known to those skilled in the art. See, for example, the techniques described in Maniatis et al., (1982) Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y., Chapter 7.

Hybridization procedures are useful for the screening of recombinant clones by using labeled mixed synthetic oligonucleotide probes where each probe is potentially the complete complement of a specific DNA sequence in the hybridization sample that includes a heterogeneous mixture of denatured double-stranded DNA. For such screening, hybridization is preferably performed on either single-stranded DNA or denatured double-stranded DNA. By using stringent hybridization conditions directed to avoid non-specific binding, it is possible, for example, to allow the autoradiographic visualization of a specific DNA clone by the hybridization of the target DNA to that single probe in the mixture which is its complete complement (Wallace, et al., (1981) Nucleic Acids Research, 9:879).

Alternatively, an expression library can be screened indirectly for a hepcidin protein of the invention having at least one epitope using antibodies to the protein. Such antibodies can both be polyclonally or monoclonally derived and used to detect an expression product indicative of the presence of a hepcidin protein. Generally, a lambda gt11 library is constructed and screened immunologically according to the method of Huynh, et al., (1985) (in DNA Cloning: A Practical Approach, D. M. Glover, ed., 1:49).

The development of specific DNA sequences encoding a hepcidin protein can also be obtained by: (1) isolation of a double stranded DNA sequence from the genomic DNA, and (2) chemical manufacture of a DNA sequence to provide the necessary codons for the protein of interest.

The polymerase chain reaction (PCR) technique can be utilized to amplify the individual members of a hepcidin family for subsequent cloning and expression of hepcidin protein cDNAs (e.g., see U.S. Pat. Nos. 4,683,202; 4,683,195; 4,889,818; Gyllenstein et al., (1988) Proc. Nat'l Acad. Sci. USA, 85:7652-7656; Ochman et al., (1988) Genetics, 120:621-623; Triglia et al., (1988) Nucl. Acids. Res., 16:8156; Frohman et al., (1988) Proc. Nat'l Acad. Sci. USA, 85:8998-9002; Loh et al., (1989) Science, 243:217-220).

Methods that are well known to those skilled in the art can be used to construct expression vectors containing a hepcidin protein or fragments thereof coding sequences and appropriate transcriptional/translational control signals. These methods include in vitro recombinant DNA techniques, synthetic techniques and in vivo recombination/genetic recombination. See, for example, the techniques described in Maniatis et al., 1982, Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y., Chapter 12.

A variety of host-expression vector systems may be utilized to express a hepcidin protein or fragment thereof. These include but are not limited to microorganisms such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing a coding sequence for a hepcidin protein or fragments thereof; yeast transformed with recombinant yeast expression vectors containing a coding sequence for a hepcidin protein or fragment

thereof; insect cell systems infected with recombinant virus expression vectors (e.g., baculovirus) containing a coding sequence for a hepcidin protein or fragment thereof; or animal cell systems infected with recombinant virus expression vectors (e.g., adenovirus, vaccinia virus) containing a coding sequence for a hepcidin protein or fragment thereof.

The expression elements of these vectors vary in their strength and specificities. Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements, including constitutive and inducible promoters, may be used in the expression vector. For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage lambda, plac, ptrp, ptac (ptrp-lac hybrid promoter) and the like may be used; when cloning in insect cell systems, promoters such as the baculovirus polyhedrin promoter may be used; when cloning in mammalian cell systems, promoters such as the adenovirus late promoter or the vaccinia virus 7.5K promoter may be used. Promoters produced by recombinant DNA or synthetic techniques may also be used to provide for transcription of the inserted coding sequence for a hepcidin protein or fragment thereof.

In yeast, a number of vectors containing constitutive or inducible promoters may be used. For reviews see, Current Protocols in Molecular Biology, Vol. 2, (1988) Ed. Ausubel et al., Greene Publish. Assoc. & Wiley Interscience Ch. 13; Grant et al., (1987) Expression and Secretion Vectors for Yeast, in Methods in Enzymology, Eds. Wu & Grossman, (1987) Acad. Press, N.Y., Vol. 153, pp. 516-544; Glover, (1986) DNA Cloning, Vol. II, IRL Press, Wash., D.C. Ch. 3; and Bitter, (1987) Heterologous Gene Expression in Yeast, Methods in Enzymology, Eds. Berger & Kimmel, Acad. Press, N.Y., Vol. 152, pp. 673-684; and The Molecular Biology of the Yeast *Saccharomyces*, (1982) Eds. Strathern et al., Cold Spring Harbor Press, Vols. I and II. For complementation assays in yeast, cDNAs for hepcidin proteins or fragments thereof may be cloned into yeast episomal plasmids (YEpl) that replicate autonomously in yeast due to the presence of the yeast 2 mu circle. A hepcidin protein or fragment thereof sequence may be cloned behind either a constitutive yeast promoter such as ADH or LEU2 or an inducible promoter such as GAL (Cloning in Yeast, Ch. 3, R. Rothstein (1986) In DNA Cloning Vol. 11, A Practical Approach, Ed. D M Glover, IRL Press, Wash., D.C.). Constructs may contain the 5' and 3' non-translated regions of a cognate hepcidin protein mRNA or those corresponding to a yeast gene. YEpl plasmids transform at high efficiency and the plasmids are extremely stable. Alternatively vectors may be used which promote integration of foreign DNA sequences into the yeast chromosome.

A particularly good expression system that could be used to express a hepcidin protein or fragments thereof is an insect system. In one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in *Spodoptera frugiperda* cells. A hepcidin protein or fragment thereof coding sequence may be cloned into non-essential regions (for example the polyhedrin gene) of the virus and placed under control of an AcNPV promoter (for example the polyhedrin promoter). Successful insertion of the polyhedrin gene results in production of non-occluded recombinant virus (i.e., virus lacking the proteinaceous coat coded for by the polyhedrin gene). These recombinant viruses are then used to infect *Spodoptera frugiperda* cells in which the inserted gene is expressed. (e.g., see Smith et al., (1983) J. Biol., 46:586; Smith, U.S. Pat. No. 4,215,051). In addition, materials and methods for baculovirus/insect cell expression systems are commercially available

in kit form from, e.g., Invitrogen, San Diego, Calif., U.S.A. (the MaxBar™ kit), and such methods are well known in the art, as described in Summers and Smith, Texas Agricultural Experiment Station Bulletin No. 1555 (1987), incorporated herein by reference. As used herein, an insect cell capable of expressing a hepcidin polynucleotide of the present invention is transformed.

In cases where an adenovirus is used as an expression vector, a hepcidin protein or fragment thereof coding sequence may be ligated to an adenovirus transcription/translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by in vivo or in vitro recombination. Insertion in a non-essential region of the viral genome (e.g., region E1 or E3) will result in a recombinant virus that is viable and capable of expressing a hepcidin protein or fragment thereof in infected hosts. (e.g., See Logan & Shenk, (1984) *Proc. Natl. Acad. Sci., (USA)* 81:3655-3659). Alternatively, the vaccinia 7.5 K promoter may be used. (e.g., see Mackett et al., (1982) *Proc. Natl. Acad. Sci., (USA)* 79:7415-7419; Mackett et al., (1984) *J. Virol.*, 49:857-864; Panicali et al., (1982) *Proc. Natl. Acad. Sci.*, 79: 4927-4931).

Specific initiation signals may also be required for efficient translation of the inserted hepcidin protein or fragment thereof coding sequences. These signals include the ATG initiation codon and adjacent sequences. In cases where the entire hepcidin protein genome, including its own initiation codon and adjacent sequences, are inserted into the appropriate expression vectors, no additional translational control signals may be needed. However, in cases where only a portion of a hepcidin protein coding sequence is inserted, exogenous translational control signals, including the ATG initiation codon, must be provided. Furthermore, the initiation codon must be in phase with the reading frame of a hepcidin protein or fragment thereof coding sequence to ensure translation of the entire insert. These exogenous translational control signals and initiation codons can be of a variety of origins, both natural and synthetic. The efficiency of expression may be enhanced by the inclusion of appropriate transcription enhancer elements, transcription terminators, etc. (see Bitter et al., (1987) *Methods in Enzymol.*, 153:516-544).

In addition, a host cell strain may be chosen which modulates the expression of the inserted sequences, or modifies and processes the gene product in the specific fashion desired. Expression driven by certain promoters can be elevated in the presence of certain inducers, (e.g., zinc and cadmium ions for metallothionein promoters). Therefore, expression of the genetically engineered hepcidin protein or fragment thereof may be controlled. This is important if the protein product of the cloned foreign gene is lethal to host cells. Furthermore, modifications (e.g., glycosylation) and processing (e.g., cleavage) of protein products may be important for the function of the protein. Different host cells have characteristic and specific mechanisms for the post-translational processing and modification of proteins. Appropriate cell lines or host systems can be chosen to ensure the correct modification and processing of the foreign protein expressed.

The host cells which contain a hepcidin protein or fragment thereof coding sequence and which express the biologically active hepcidin protein or fragment thereof gene product may be identified by at least four general approaches: (a) DNA-DNA hybridization; (b) the presence or absence of "marker" gene functions; (c) assessing the level of transcription as measured by expression of hepcidin protein mRNA transcripts in host cells; and (d) detection of hepcidin protein gene products as measured by immunoassays or by its biological activity.

In the first approach, the presence of a hepcidin protein or fragment thereof coding sequence inserted in the expression vector can be detected by DNA-DNA hybridization using probes comprising nucleotide sequences that are homologous to a hepcidin protein coding sequence or particular portions thereof substantially as described recently (Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819).

In the second approach, the recombinant expression vector/host system can be identified and selected based upon the presence or absence of certain "marker" gene functions (e.g., thymidine kinase activity, resistance to antibiotics, resistance to methotrexate, transformation phenotype, occlusion body formation in baculovirus, etc.). For example, if a hepcidin protein or fragment thereof coding sequence is inserted within a marker gene sequence of the vector, recombinants containing a hepcidin protein or fragment thereof coding sequence can be identified by the absence of the marker gene function. Alternatively, a marker gene can be placed in tandem with a hepcidin protein or fragment thereof coding sequence under the control of the same or different promoter used to control the expression of a hepcidin coding sequence. Expression of the marker in response to induction or selection indicates expression of a hepcidin protein coding sequence.

In the third approach, transcriptional activity for a hepcidin protein or fragment thereof coding region can be assessed by hybridization assays. For example, RNA can be isolated and analyzed by Northern blot using a probe homologous to a hepcidin protein or fragment thereof coding sequence or particular portions thereof substantially as described (Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819). Alternatively, total nucleic acids of the host cell may be extracted and assayed for hybridization to such probes.

In the fourth approach, the expression of a hepcidin protein or fragment thereof product can be assessed immunologically, for example by Western blots, immunoassays such as radioimmunoprecipitation, enzyme-linked immunoassays and the like.

Once a recombinant that expresses a hepcidin protein or fragment thereof is identified, the gene product should be analyzed. This can be achieved by assays based on the physical, immunological or functional properties of the product. For example, the methods of the invention include a process for producing a hepcidin protein in which a host cell containing a suitable expression vector that includes a hepcidin polynucleotide of the invention is cultured under conditions that allow expression of the encoded hepcidin protein. A hepcidin protein can be recovered from the culture, conveniently from the culture medium, or from a lysate prepared from the host cells and further purified. Preferred embodiments include those in which the protein produced by such process is a full length or mature form of the protein.

The present invention further provides isolated hepcidin protein encoded by the nucleic acid fragments of the present invention or by degenerate variants of the nucleic acid fragments of the present invention. By "degenerate variant" is intended nucleotide fragments that differ from a nucleic acid fragment of the present invention (e.g., an ORF) by nucleotide sequence but, due to the degeneracy of the genetic code, encode an identical protein sequence. Preferred nucleic acid fragments of the present invention are the Orbs that encode proteins.

A hepcidin protein of the present invention can alternatively be purified from cells that have been altered to express a hepcidin protein. As used herein, a cell is altered to express a desired polypeptide or protein when the cell, through genetic manipulation, is made to produce a hepcidin protein which it normally does not produce or which the cell normally

produces at a lower level. One skilled in the art can readily adapt procedures for introducing and expressing either recombinant or synthetic sequences into eukaryotic or prokaryotic cells in order to generate a cell which produces a hepcidin protein of the present invention.

A hepcidin protein of the invention may also be expressed as a product of transgenic animals, e.g., as a component of the milk of transgenic cows, goats, pigs, or sheep which are characterized by somatic or germ cells containing a nucleotide sequence encoding a hepcidin protein.

A hepcidin protein may also be produced by known conventional chemical synthesis. Methods for constructing a hepcidin protein of the present invention by synthetic means are known to those skilled in the art. The synthetically-constructed hepcidin protein sequences, by virtue of sharing primary, secondary or tertiary structural and/or conformational characteristics with natural hepcidin protein may possess biological properties in common therewith, including protein activity. Thus, they may be employed as biologically active or immunological substitutes for a natural, purified hepcidin protein in screening of therapeutic compounds and in immunological processes for the development of antibodies.

A hepcidin protein of the invention may be prepared by culturing transformed host cells under culture conditions suitable to express the recombinant protein. The resulting expressed hepcidin protein may then be purified from such culture (i.e., from culture medium or cell extracts) using known purification processes, such as gel filtration and ion exchange chromatography. The purification of a hepcidin protein may also include an affinity column containing agents which will bind to the protein; one or more column steps over such affinity resins as concanavalin A-agarose, heparin-toyopearl™ or Cibacrom blue 3GA Sepharose™; one or more steps involving hydrophobic interaction chromatography using such resins as phenyl ether, butyl ether, or propyl ether; or immunoaffinity chromatography.

Alternatively, a hepcidin protein of the invention may also be expressed in a form that will facilitate purification. For example, it may be expressed as a fusion protein, such as those of maltose binding protein (MBP), glutathione-S-transferase (GST) or thioredoxin (TRX), or as a His tag. Kits for expression and purification of such fusion proteins are commercially available from New England BioLab (Beverly, Mass.), Pharmacia (Piscataway, N.J.) and Invitrogen, respectively. A hepcidin protein can also be tagged with an epitope and subsequently purified by using a specific antibody directed to such epitope. One such epitope ("FLAG®") is commercially available from Kodak (New Haven, Conn.).

Other fragments and derivatives of the sequences of hepcidin proteins/peptides which would be expected to retain protein activity in whole or in part (e.g., binding to a TIR2 receptor, binding to a hepcidin specific antibody, etc.) and are useful for screening or other immunological methodologies may also be easily made by those skilled in the art given the disclosures herein. Such modifications are encompassed by the present invention.

A hepcidin protein or fragment thereof should be immunoreactive whether it results from the expression of the entire gene sequence, a portion of the gene sequence or from two or more gene sequences which are ligated to direct the production of chimeric proteins. This reactivity may be demonstrated by standard immunological techniques, such as radioimmunoprecipitation, radioimmune competition, or immunoblots.

Generation of Antibodies that Define a Hepcidin Protein

Various procedures known in the art may be used for the production of antibodies to the mid-portion (amino acids 20 to 50) or C-terminus of epitopes (amino acids 65 to 84) of a hepcidin protein of SEQ ID NO: 2. The hepcidin specific antibodies bind those epitopes and no other known sequences. Such antibodies include but are not limited to polyclonal, monoclonal, chimeric, single chain, Fab fragments and an Fab expression library. For the production of antibodies, various host animals may be immunized by injection with a particular hepcidin protein, or a synthetic hepcidin protein, including but not limited to rabbits, mice, rats, etc. Various adjuvants may be used to increase the immunological response, depending on the host species, including but not limited to Freund's (complete and incomplete), mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanin, dinitrophenol, and potentially useful human adjuvants such as BCG (bacille Calmette-Guerin) and corynebacterium parvum.

Polyclonal antibodies may be readily generated by one of ordinary skill in the art from a variety of warm-blooded animals such as horses, cows, various fowl, rabbits, mice, or rats. Briefly, hepcidin is utilized to immunize the animal through intraperitoneal, intramuscular, intraocular, or subcutaneous injections, an adjuvant such as Freund's complete or incomplete adjuvant. Following several booster immunizations, samples of serum are collected and tested for reactivity to hepcidin. Particularly preferred polyclonal antisera will give a signal on one of these assays that is at least three times greater than background. Once the titer of the animal has reached a plateau in terms of its reactivity to hepcidin, larger quantities of antisera may be readily obtained either by weekly bleedings, or by exsanguinating the animal.

Monoclonal antibodies to peptides of hepcidin may be prepared by using any technique that provides for the production of antibody molecules by continuous cell lines in culture. These include but are not limited to the hybridoma technique originally described by Kohler and Milstein, (Nature, (1975) 256:495-497), the more recent human B-cell hybridoma technique (Kosbor et al., (1983) Immunology Today, 4:72) and the EBV-hybridoma technique (Cole et al., (1985) Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, Inc., pp. 77-96). In an additional embodiment of the invention monoclonal antibodies specific to hepcidin proteins/peptides may be produced in germ-free animals utilizing recent technology (PCT/US90/02545). According to the invention, human antibodies may be used and can be obtained by using human hybridomas (Cote et al., (1983) Proc. Natl. Acad. Sci., 80:2026-2030) or by transforming human B cells with EBV virus in vitro (Cole et al., (1985) in, Monoclonal Antibodies and Cancer Therapy, Alan R. Liss, pp. 77-96). In fact, according to the invention, techniques developed for the production of "chimeric antibodies" (Morrison et al., (1984) Proc. Natl. Acad. Sci., 81:6851-6855; Neuberger et al., (1984) Nature, 312:604-608; Takeda et al., (1985) Nature, 314:452-454) by splicing the genes from a mouse antibody molecule of appropriate antigen specificity together with genes from a human antibody molecule of appropriate biological activity can be used; such antibodies are due to this invention.

According to the invention, techniques described for the production of single chain antibodies (U.S. Pat. No. 4,946,778) can be adapted to produce hepcidin protein-specific single chain antibodies.

An additional embodiment of the invention utilizes the techniques described for the construction of Fab expression libraries (Huse et al., (1989) Science, 246:1275-1281) to

allow rapid and easy identification of monoclonal Fab fragments with the desired specificity to hepcidin proteins/peptides.

Antibody fragments that contain specific binding sites for a hepcidin protein may be generated by known techniques. For example, such fragments include but are not limited to: the $F(ab')_2$ fragments which can be produced by pepsin digestion of the antibody molecule and the Fab fragments which can be generated by reducing the disulfide bridges of the $F(ab')_2$ fragments.

Diagnostic Assays and Kits

Yet another purpose of the present invention is to provide reagents for use in diagnostic assays for the detection of a hepcidin protein from individuals suffering from hemochromatosis, iron deficiency anemia, hemosiderosis, liver cirrhosis and such other diseases described herein.

In one mode of this embodiment, a hepcidin protein of the present invention may be used as an antigen in immunoassays for the detection of those individuals suffering from hemochromatosis, iron deficiency anemia, hemosiderosis, liver cirrhosis and such other diseases described herein. A hepcidin protein, polypeptide and/or peptide of the present invention may be used in any immunoassay system known in the art including, but not limited to: radioimmunoassays, enzyme-linked immunosorbent assay, "sandwich" assays, precipitin reactions, gel diffusion immunodiffusion assays, agglutination assays, fluorescent immunoassays, protein A immunoassays and immunoelectrophoresis assays, to name but a few U.S. Pat. No. 4,629,783 and patents cited therein also describe suitable assays.

According to the present invention, monoclonal or polyclonal antibodies produced to various forms of a hepcidin protein, can be used in an immunoassay on samples of blood, spinal fluid or other body fluid to diagnose subjects with hemochromatosis, iron deficiency anemia, hemosiderosis, liver cirrhosis and other diseases described herein.

In one embodiment of the invention, a sample of blood is removed from the patient by venesection and placed in contact with an anticoagulant such as EDTA, mixed, centrifuged at 600 g for 10 min and the plasma removed as is common in the art or a sample of spinal fluid is removed from the patient by lumbar puncture.

The antibodies described herein may be used as the basic reagents in a number of different immunoassays to determine the presence of a hepcidin protein in a sample of tissue, blood or body fluid. Generally speaking, the antibodies can be employed in any type of immunoassay, whether qualitative or quantitative. This includes both the two-site sandwich assay and the single site immunoassay of the non-competitive type, as well as in traditional competitive binding assays.

Particularly preferred, for ease of detection, and its quantitative nature, is the sandwich or double antibody assay, of which a number of variations exist, all of which are intended to be encompassed by the present invention.

For example, in a typical forward sandwich assay, unlabeled antibody is immobilized on a solid substrate, e.g., microtiter plate wells, and the sample to be tested is brought into contact with the bound molecule. After a suitable period of incubation, for a period of time sufficient to allow formation of an antibody-antigen binary complex, a second antibody, labelled with a reporter molecule capable of inducing a detectable signal, is then added and incubation is continued allowing sufficient time for binding with the antigen at a different site and the formation of a ternary complex of antibody-antigen-labeled antibody. Any unreacted material is washed away, and the presence of the antigen is determined by observation of a signal, which may be quantitated by

comparison with a control sample containing known amounts of antigen. Variations on the forward sandwich assay include the simultaneous assay, in which both sample and antibody are added simultaneously to the bound antibody, or a reverse sandwich assay in which the labelled antibody and sample to be tested are first combined, incubated and added to the unlabelled surface bound antibody. These techniques are well known to those skilled in the art, and the possibility of minor variations will be readily apparent. As used herein, "sandwich assay" is intended to encompass all variations on the basic two-site technique.

For the sandwich assays of the present invention, the only limiting factor is that both antibodies have different binding specificities for a hepcidin protein. Thus, a number of possible combinations are possible.

As a more specific example, in a typical forward sandwich assay, a primary antibody is either covalently or passively bound to a solid support. The solid surface is usually glass or a polymer, the most commonly used polymers being cellulose, polyacrylamide, nylon, polystyrene, polyvinylchloride or polypropylene. The solid supports may be in the form of tubes, beads, discs or microplates, or any other surfaces suitable for conducting an immunoassay. The binding processes are well known in the art. Following binding, the solid phase-antibody complex is washed in preparation for the test sample. An aliquot of the body fluid containing a hepcidin protein to be tested is then added to the solid phase complex and incubated at 25° C. for a period of time sufficient to allow binding of any hepcidin protein present to the antibody specific for hepcidin protein. The second antibody is then added to the solid phase complex and incubated at 25° C. for an additional period of time sufficient to allow the second antibody to bind to the primary antibody-antigen solid phase complex. The second antibody is linked to a reporter molecule, the visible signal of which is used to indicate the binding of the second antibody to any antigen in the sample. By "reporter molecule", as used in the present specification is meant a molecule which by its chemical nature, provides an analytically detectable signal which allows the detection of antigen-bound antibody. Detection must be at least relatively quantifiable, to allow determination of the amount of antigen in the sample, this may be calculated in absolute terms, or may be done in comparison with a standard (or series of standards) containing a known normal level of antigen.

The most commonly used reporter molecules in this type of assay are either enzymes or fluorophores. In the case of an enzyme immunoassay an enzyme is conjugated to the second antibody, often by means of glutaraldehyde or periodate. As will be readily recognized, however, a wide variety of different conjugation techniques exist, which are well known to the skilled artisan. Commonly used enzymes include horseradish peroxidase, glucose oxidase, beta-galactosidase and alkaline phosphatase, among others. The substrates to be used with the specific enzymes are generally chosen for the production, upon hydrolysis by the corresponding enzyme, of a detectable color change. For example, p-nitrophenyl phosphate is suitable for use with alkaline phosphatase conjugates; for peroxidase conjugates, 1,2-phenylenediamine or toluidine are commonly used. It is also possible to employ fluorogenic substrates, which yield a fluorescent product rather than the chromogenic substrates noted above. In all cases, the enzyme-labelled antibody is added to the first antibody-hepcidin protein complex and allowed to bind to the complex, and then the excess reagent is washed away. A solution containing the appropriate substrate is then added to the tertiary complex of antibody-antigen-labeled antibody. The substrate reacts with the enzyme linked to the second antibody, giving

a qualitative visual signal, which may be further quantitated, usually spectrophotometrically, to give an evaluation of the amount of antigen that is present in the serum sample.

Alternately, fluorescent compounds, such as fluorescein or rhodamine, may be chemically coupled to antibodies without altering their binding capacity. When activated by illumination with light of a particular wavelength, the fluorochrome-labelled antibody absorbs the light energy, inducing a state of excitability in the molecule, followed by emission of the light at a characteristic longer wavelength. The emission appears as a characteristic color visually detectable with a light microscope. As in the enzyme immunoassay (EIA), the fluorescent-labelled antibody is allowed to bind to the first antibody-hepcidin protein complex. After washing the unbound reagent, the remaining ternary complex is then exposed to light of the appropriate wavelength, and the fluorescence observed indicates the presence of the antigen. Immunofluorescence and EIA techniques are both very well established in the art and are particularly preferred for the present method. However, other reporter molecules, such as radioisotopes, chemiluminescent or bioluminescent molecules may also be employed. It will be readily apparent to the skilled artisan how to vary the procedure to suit the required use.

Alternatively, the sample to be tested either human blood or spinal fluid containing a hepcidin protein may be used in a single site immunoassay wherein it is adhered to a solid substrate either covalently or noncovalently. An unlabeled anti-hepcidin protein antibody is brought into contact with the sample bound on the solid substrate. After a suitable period of incubation, for a period of time sufficient to allow formation of an antibody-antigen binary complex a second antibody, labelled with a reporter molecule capable of inducing a detectable signal, is then added and incubation is continued allowing sufficient time for the formation of a ternary complex of antigen-antibody-labeled antibody. For the single site immunoassay, the second antibody may be a general antibody (i.e., xenogeneic antibody to immunoglobulin, particularly anti-(IgM and IgG) linked to a reporter molecule) that is capable of binding an antibody that is specific for a hepcidin protein of interest.

A hepcidin gene (mutated or normal) can be utilized in an assay of iron metabolism. The gene is expressed, with or without any accompanying molecules, in cell lines or primary cells derived from human or animal subjects, healthy subjects, or cells from other organisms (such as rodents, insects, bacteria, amphibians, etc.). Uptake of iron by these cells is measured, for example through the use of radioactive isotopes. Further, binding of iron to a hepcidin gene product can also be measured. Such experiments assist in assessing the role of a hepcidin gene and hepcidin gene product in iron uptake, binding, and transport by and in cells.

Therapeutic Treatment

In one aspect of the invention, the hepcidin diagnostic methods and kits can be used in genetic technological approaches, such as for over expressing or down regulating hepcidin. In certain therapeutic applications, it is desirable to down regulate the expression and/or function of a hepcidin gene, a mutant hepcidin gene, a hepcidin protein, or a mutant hepcidin protein. For example, down regulation of a normal hepcidin gene or a normal hepcidin protein is desirable in situations where iron is under accumulated in the body, for example in certain anemias (i.e., thalassaemias, hemolytic anemias, transfusions). On the other hand, down regulation of a mutant hepcidin gene or a hepcidin protein is desirable in situations where iron is over accumulated in the body.

As discussed above antibodies specific to a normal or a mutant hepcidin protein can be prepared. Such antibodies can be used therapeutically in the diseases described herein. For example, to block the action of a mutant or normal hepcidin gene if the function associated with a mutant protein is an up regulation of a normal hepcidin protein function and leads to an over accumulation of iron in the body. Similarly, antibodies can be used therapeutically to block action of a hepcidin protein that is causing an under accumulation of iron in the body.

In a similar manner, a hepcidin gene, either in a normal or in a mutant form, can be down regulated through the use of antisense oligonucleotides directed against the gene or its transcripts. A similar strategy can be utilized as discussed above in connection with antibodies. For a particularly valuable review of the design considerations and use of antisense oligonucleotides, see Uhlmann et al., (1990) *Chemical Reviews* 90:543-584, the disclosure of which is hereby incorporated by reference. The antisense oligonucleotides of the present invention may be synthesized by any of the known chemical oligonucleotide synthesis methods. Such methods are generally described, for example, in Winnacker Chirurg (1992) 63:145. Antisense oligonucleotides are most advantageously prepared by utilizing any of the commercially available, automated nucleic acid synthesizers. One such device, the Applied Biosystems 380B DNA Synthesizer, utilizes beta-cyanoethyl phosphoramidite chemistry.

Since the complete nucleotide synthesis of DNA complementary to a hepcidin gene is known, the mRNA transcript of the cDNA sequence is also known. As such, antisense oligonucleotides hybridizable with any portion of such transcripts may be prepared by oligonucleotide synthesis methods known to those skilled in the art. While any length oligonucleotide may be utilized in the practice of the invention, sequences shorter than 12 bases may be less specific in hybridizing to the target mRNA, may be more easily destroyed by enzymatic digestion, and may be destabilized by enzymatic digestion. Hence, oligonucleotides having 12 or more nucleotides are preferred. Long sequences, particularly sequences longer than about 40 nucleotides, may be somewhat less effective in inhibiting translation because of decreased uptake by the target cell. Thus, oligomers of 12-40 nucleotides are preferred, more preferably 15-30 nucleotides, most preferably 18-26 nucleotides. Sequences of 18-24 nucleotides are most particularly preferred.

In still another aspect of the invention, hepcidin can be used in the therapy of the disorders described herein, by treating subjects with hepcidin, and agonists or antagonists of hepcidin. Iron uptake in cells can be modulated by varying the concentration of hepcidin, and/or inhibiting hepcidin binding to iron or to the transferrin receptor. Accordingly, hepcidin, and agonists or antagonists of hepcidin may be useful in the treatment of conditions where there is a disturbance in iron metabolism. For example, such substances may be useful in the treatment of conditions such as haemochromatosis, neurodegenerative diseases, ischemic tissue damage, including ischemic stroke or trauma, heart disease, and tumors, in particular skin cancer and such other diseases described herein. Some have evidence of the end organ injury seen with prolonged iron overload including liver cirrhosis, arthritis, diabetes, and hypogonadism. Fleming et al., *Proc. Natl. Acad. Sci. USA* 99, 10653-10658 (2002).

The invention also contemplates methods of modulating iron metabolism using hepcidin. In particular, the present invention relates to a method for treating conditions involving disturbances in iron metabolism comprising administering an iron-modulating amount of hepcidin, or a stimulant, agonist

or antagonist of hepcidin. Conditions involving disturbances in iron metabolism which may be treated using the method of the invention include by way of example haemochromatosis, neurodegenerative diseases, ischemic tissue damage, including ischemic stroke or trauma, heart disease, and tumors, in particular skin cancer and such other diseases described herein. A substance which is an agonist or antagonist of hepcidin may be identified by determining the effect of the substance on the binding activity of hepcidin and iron, or hepcidin and the transferrin receptors TfR1 or TfR2, or the effect of the substance on the expression of hepcidin in cells capable of expressing hepcidin including cells genetically engineered to express hepcidin on their surface.

The invention therefore in one aspect relates to a method of identifying agonists or antagonists of hepcidin comprising reacting a substance suspected of being an agonist or antagonist of hepcidin with hepcidin and iron under conditions such that hepcidin is capable of binding to iron; measuring the amount of hepcidin bound to iron; and determining the effect of the substance by comparing the amount of hepcidin bound to iron with an amount determined for a control. The invention also relates to a method of identifying agonists or antagonists of hepcidin comprising reacting a substance suspected of being an agonist or antagonist of hepcidin with hepcidin and transferrin receptor under conditions such that hepcidin is capable of binding to the transferrin receptor; measuring the amount of hepcidin bound to a transferrin receptor; and determining the effect of the substance by comparing the amount of hepcidin bound to a transferrin receptor with an amount determined for a control.

The invention also relates to a method of identifying agonists or antagonists of hepcidin comprising reacting a substance suspected of being an agonist or antagonist of hepcidin with a cell which produces hepcidin, measuring the amount of hepcidin expressed by the cell, and determining the effect of the substance by comparing the amount of expression of hepcidin with an amount determined for a control. The invention further relates to a method for identifying an agonist or antagonist of hepcidin-mediated iron uptake comprising: incubating a cell expressing hepcidin on its surface and a substance suspected of being an agonist or antagonist of hepcidin in the presence of iron and in the absence of transferrin, measuring the amount of iron uptake into the cell, and identifying an agonist or antagonist of hepcidin-mediated iron uptake by comparing the amount of iron uptake in the cell with the amount of iron uptake in a cell from a control incubation in the absence of the substance.

In some embodiments of the invention, hepcidin peptides are provided for therapeutic use in subjects having symptoms of a primary iron overload disease or syndrome, such as hemochromatosis, or other iron overload condition caused by secondary causes, such as repeated transfusions. A hepcidin peptide can be full-length hepcidin or some fragment of hepcidin. Preferably, a hepcidin peptide comprises the amino acid residues 28 to 47 or 70 to 80 of a hepcidin of SEQ ID NO: 2. The predicted amino acid sequence and genomic and cDNA sequences of hepcidin were provided in (Krause et al., (2000) FEBS Lett. 480, 147-150; Pigeon et al., (2001) J. Biol. Chem. 276, 7811-7819), hereby incorporated by reference in their entirety. A hepcidin protein or fragment thereof may be administered with beta-2-microglobulin, such as in the form of a complex. In some embodiments, a hepcidin protein greater than about 20 amino acids is administered in a complex with beta-2-microglobulin.

In some embodiments of the invention, agonists or antagonists of a hepcidin protein or a transferrin receptor are provided. Agonists of a hepcidin polypeptide, and/or antagonists

of a transferrin receptor, are useful for example, in the treatment of primary or secondary iron overload diseases or syndromes, while antagonists of a hepcidin polypeptide, or agonists of the transferrin receptor are useful, for example, in the treatment of iron deficiency conditions, such as anemias. In other embodiments, mutant hepcidin proteins/peptides are provided which function as antagonists of the wild-type hepcidin protein. Antagonists or agonists can also be antibodies, directed against a transferrin receptor, or the mid-portion (amino acids 20 to 50) or C-terminal region (amino acids 65 to 84) of a hepcidin protein of SEQ ID NO: 2. In some embodiments of the invention, hepcidin polypeptides can serve as antagonists of a transferrin receptor. In further embodiments of the invention, peptidomimetics can be designed using techniques well known in the art as antagonists or agonists of a hepcidin protein and/or a transferrin receptor.

Ligands for a transferrin receptor, whether antagonists or agonists, can be screened using the techniques described herein for the ability to bind to a transferrin receptor. Additionally, competition for hepcidin binding to a transferrin receptor can be done using techniques well known in the art. Ligands, or more generally, binding partners for a hepcidin protein can be screened, for example, for the ability to inhibit the complexing of a hepcidin polypeptide to beta-2-microglobulin, using techniques described herein.

In some embodiments of the invention, agonists or antagonists of transferrin are similarly utilized to increase or decrease the amount of iron transported into a cell, such as into a patient's hepatocytes or lymphocytes. For example, the efficacy of a drug, therapeutic agent, agonist, or antagonist can be identified in a screening program in which modulation is monitored in in vitro cell systems. Host cell systems that express various mutant hepcidin proteins/peptides and are suited for use as primary screening systems. Candidate drugs can be evaluated by incubation with these cells and measuring cellular functions dependent on a hepcidin gene or by measuring proper hepcidin protein folding or processing. Such assays might also entail measuring receptor-like activity, iron transport and metabolism, gene transcription or other upstream or downstream biological function as dictated by studies of hepcidin gene function.

Alternatively, cell-free systems can be utilized. Purified hepcidin protein can be reconstituted into artificial membranes or vesicles and drugs screened in a cell-free system. Such systems are often more convenient and are inherently more amenable to high throughput types of screening and automation.

Criteria for the determination of the purity of a hepcidin protein include those standard to the field of protein chemistry. These include N-terminal amino acid determination, one and two-dimensional polyacrylamide gel electrophoresis, and silver staining. The purified protein is useful for use in studies related to the determination of secondary and tertiary structure, as aid in drug design, and for in vitro study of the biological function of the molecule.

In some embodiments of the invention, drugs can be designed to modulate a hepcidin gene and a hepcidin protein activity from knowledge of the structure and function correlations of a known hepcidin protein. For this, rational drug design by use of X-ray crystallography, computer-aided molecular modeling (CAMP), quantitative or qualitative structure-activity relationship (QSAR), and similar technologies can further focus drug discovery efforts. Rational design allows prediction of protein or synthetic structures that can interact with and modify a hepcidin protein activity. Such structures may be synthesized chemically or expressed in

biological systems. This approach has been reviewed in Capsey et al., *Genetically Engineered Human Therapeutic Drugs*, Stockton Press, New York (1988). Further, combinatorial libraries can be designed, synthesized and used in screening programs.

In order to administer therapeutic agents based on, or derived from, the present invention, it will be appreciated that suitable carriers, excipients, and other agents may be incorporated into the formulations to provide improved transfer, delivery, tolerance, and the like.

A multitude of appropriate formulations can be found in the formulary known to all pharmaceutical chemists: Remington's *Pharmaceutical Sciences*, (15th Edition, Mack Publishing Company, Easton, Pa. (1975)), particularly Chapter 87, by Blaug, Seymour, therein. These formulations include for example, powders, pastes, ointments, jelly, waxes, oils, lipids, anhydrous absorption bases, oil-in-water or water-in-oil emulsions, emulsions carbowax (polyethylene glycols of a variety of molecular weights), semi-solid gels, and semi-solid mixtures containing carbowax.

Any of the foregoing formulations may be appropriate in treatments and therapies in accordance with the present invention, provided that the active agent in the formulation is not inactivated by the formulation and the formulation is physiologically compatible.

The invention is not limited to the embodiments described herein and may be modified or varied without departing from the scope of the invention.

EXAMPLES

Tissues and Tissue Preparation

Human liver samples (n=7) used in the present study were obtained after hemi-hepatectomy in adult subjects with liver metastases. Healthy tissues were fixed in 4% paraformaldehyde for immunohistochemistry or immediately frozen in liquid nitrogen for RT PCR, Western blot and immunofluorescence analysis.

Guinea pigs (n=7) and mice (n=S) were anesthetized and subsequently sacrificed by cervical dislocation. Tissue specimens from liver, skeletal muscle and heart were resected and immediately frozen in liquid nitrogen for Western blot analysis or fixed in paraformaldehyde.

Peptide Synthesis, Immunization Procedure, and Antibodies

From the published prohepcidin sequence (Krause et al., (2000) *FEBS Lett.* 480, 147-150; Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819), the peptides hepcidin-(28-47) (SEQ ID NO: 3) and hepcidin-(70-84) (SEQ ID NO: 4) were synthesized as C terminal amides using a standard Fmoc protocol (Cetin et al., (1994), *Proc. Natl. Acad. Sci. USA* 91, 2935-2939). Peptides were coupled to keyhole limpet hemocyanin using m-maleimidobenzoyl-N-hydroxysuccinimide ester, and two SPF rabbits (Charles River Iffa Credo) were immunized with each peptide conjugate (Eurogentec, Seraing, Belgium). After testing the titer by ELISA, three antisera [EG (1)-HepC directed against hepcidin-(70-84) and EG(1)-HepN and EG(2)-HepN, each directed against hepcidin-(28-47)] were used in the present study (hepcidin 28-47: PQQ TGQ LAE LQP QDR AGA RA SEQ. (SEQ ID NO: 3), hepcidin 70-84: CGC CHR SKC GMC CKT (SEQ ID NO: 4)). The peptide epitopes used for the generation of the antisera displayed no homology to any hitherto reported protein as confirmed by the BLAST P2 search.

The BT-TFR21 S antibody against mouse Tfr2 (BioTrend, Cologne, Germany) was raised against the cytoplasmic N-terminus of mouse Tfr2-alpha (Tfr2) is alternatively spliced to

alpha and beta isoforms, see Fleming et al., (2000) *Proc. Natl. Acad. Sci. USA* 97, 2214-2219), showing 68% sequence homology to the corresponding region of human Tfr2-alpha. The antibody was generated in rabbits and affinity purified.

Expression Analyses in the Human Liver

RNA isolation was performed using Qiagen RNA easy kit including DNA digestion. Reverse transcription (RT)-PCR analysis was performed as described previously (Kulaksiz et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 6796-6801; Kulaksiz et al., (2002) *Am. J. Pathol.* 161, 655-664) using the following primers and specifications given in 5-3' orientation: human hepcidin (GenBank database accession no. NM0211175), 5'-CTG CAA CCC CAG GAC AGA G-3' (SEQ ID NO: 5) and 5'-GGA ATA AAT AAG GAA GGG AGG GG-3' (SEQ ID NO: 6), corresponding to nucleotide positions 147-165 and 338-316. Human Tfr2 (#AF067864), 5'-GAT TCA GGG TCA GGG AGG TG-3' (SEQ ID NO: 7) and 5'-GAA GGG GOT GTG ATT GAA GG-3' (SEQ ID NO: 8); corresponding to nucleotide positions 2496-2515 and 2694-2675. After an initial denaturation of 94° C. for 4 min; reactions were subjected to 35 cycles of the following thermal program: 94° C. for 30 s, 60° C. for 30 s, and 72° C. for 30 s; this program was followed by a final 5 min elongation step at 72° C. Amplification products were run on an ethidium bromide-stained 1.8% 89 mM Tris/89 mM boric acid/2 mM EDTA (pH 8.3) agarose gel. The amplification of significant levels of genomic DNA was excluded by appropriate controls.

Expression Analyses IN HepG2 Cells

The human hepatoma HepG2 cells were obtained from the German Collection of Microorganisms and Cell Culture (Braunschweig, Germany) and grown at 37° C. in 5% CO₂ in RPMI 1640 media (Gibco, Karlsruhe, Germany) supplemented with 10% (vol/vol) heat-inactivated FBS, penicillin (100 units/ml), and streptomycin (100 mg/ml). Cells were analyzed by RT PCR using the primer specifications mentioned above. For immunofluorescence microscopy, HepG2 cells were grown on glass slides fixed for 4 min in methanol, and permeabilized with 0.5% Triton X-100 in PBS. After incubation with hepcidin (1:2000) and Tfr2 antibodies (1:1000) for 60 min, followed by incubation with Cy-3-conjugated anti-rabbit antibody (Dianova, Hamburg, Germany), the immunostaining was investigated under an Olympus AX70 microscope using appropriate filters.

Extraction of Hepcidin and Tfr2 from Tissues and HepG2 Cells

For hepcidin analysis, frozen tissues and HepG2 cells were mixed in 1 M acetic acid and boiled for 8 min as described (Cetin et al., (1994), *Proc. Natl. Acad. Sci. USA* 91, 2935-2939; Cetin et al., (1995) *Proc. Natl. Acad. Sci. USA* 92, 5925-5929). After homogenization with an Ultra-Turrax homogenizer (Janke & Kunkel, Staufen, Germany) the samples were centrifuged at 20,000xg for 20 min at 4° C. and the supernatants were filtered through a 0.45-mm pore size filter. To enrich proteins, cell and total tissue extracts were applied to an octadecasilyl (C 18) Sep-Pak cartridge (Waters, Mass.). The column was washed with 0.01 M HCl and eluted with 30% (vol/vol) 2-propanol/30% (vol/vol) methanol 0.01 M HCl (Cetin et al., (1994), *Proc. Natl. Acad. Sci. USA* 91, 2935-2939). Protein fractions were lyophilized and stored at -80° C. until use. For Tfr2 analysis, tissues and cells were homogenized in Tris-HCl buffer containing 100 mM NaCl, 50 mM Tris-HCl, pH 7.4, 10% glycerol, 1% Triton X-100, 2 mg/ml leupeptin, 2 mg/ml pepstatin, and 1 mM phenylmethylsulfonyl fluoride, and centrifuged at 100,000 g for 30 min at 4° C.

Immunoblot Analysis

For Western blot analysis, protein extracts were incubated for 7 min at 94° C. in sample buffer with 4% (wt/vol) SDS (Merck, Darmstadt, Germany), 50 mM Tris-HCl (pH 8.15), 1 mM EDTA, 3.24 mM dithiothreitol (Roth, Karlsruhe, Germany), 12.5% (wt/vol) glycerol (Merck), and 0.002% bromophenol blue (Merck). To detect hepcidin, a 16.5% tricine-SDS-polyacrylamide gel was used according to the protocols published (Cetin et al., (1994), *Proc. Natl. Acad. Sci. USA* 91, 2935-2939; Kulaksiz et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 6796-6801; Kulaksiz et al., (2002) *Am. J. Pathol.* 161, 655-664; Cetin et al., (1995) *Proc. Natl. Acad. Sci. USA* 92, 5925-5929). Tfr2 immunoblots were performed using 8% SDS-polyacrylamide gels. Following electrophoresis, proteins were transferred onto hydrophobic polyvinylidene fluoride-based membranes (Pall, Portsmouth, England) by semidry blotting. The membranes were incubated overnight with hepcidin or Tfr2 antibodies at dilutions mentioned above. After washing in Tris-buffered saline containing 10 mM Tris-HCl (pH 8.0), 150 mM NaCl, and 0.05% Tween 20, the respective immunoreactive proteins were visualized after incubation with alkaline phosphatase-conjugated goat anti-rabbit antibody (diluted 1:50,000; Sigma) using nitro blue tetrazolium and 5-bromo-4-chloro-3-indolyl phosphate as chromogens (Sigma). The immunoreaction on the Western blot was specifically blocked after preincubation of the antibodies with the corresponding peptide immunogens. Cross-reactivity with the second goat anti-rabbit antibody was excluded by appropriate controls (Kulaksiz et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 6796-6801; Kulaksiz et al., (2002) *Am. J. Pathol.* 161, 655-664).

Immunohistochemistry and Immunofluorescence

Tissues were fixed in 4% paraformaldehyde for 18 h at 4° C. After dehydration in graded ethanol series, the specimens were embedded in paraffin. Paraffin sections (5 μ m) were immunostained for hepcidin (antibodies EG(1)-HepN, Kci (2)-HepN, and EG(1)-HepC, each diluted 1:2000) or Tfr2 (antibody BT-TFR21-S, diluted 1:1000) by the avidin-biotin-peroxidase complex (ABC) technique and incubation sequences as previously described (Kulaksiz et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 6796-6801; Kulaksiz et al., (2002) *Am. J. Pathol.* 161, 655-664). The sections were incubated with the respective antibodies for 24 h at 4° C., followed by incubation with biotinylated anti-rabbit IgG (Jackson ImmunoResearch, West Grove, Pa., USA) for 30 min diluted 1:200. The sections were then incubated for 30 min with a preformed complex of biotin-peroxidase/streptavidin (Jackson ImmunoResearch), diluted in PBS (final concentrations: biotin-peroxidase, 0.7 mg/ml; streptavidin, mg/ml). The antigen-antibody binding sites were visualized by incubation of the sections in 0.7 mM diaminobenzidine hydrochloride/0.0020% H₂O₂ in 0.05 M Tris-HCl pH 7.6).

For immunofluorescence microscopy, tissue sections from human liver (2-4 mm) were prepared with a cryotome (FrigoCut 2800E; Leica, Nussloch, Germany), air dried for 2 hours, and fixed for 10 min in cold acetone (-20° C.). Double-immunofluorescence labeling was performed as described previously (Rost et al., (1999) *Hepatology* 29, 814-821) using the specific hepcidin antibodies (diluted 1:1000) and monoclonal antibody C219 (id.) raised against canalicular P-glycoproteins (Centocor, Malvern, Pa.) diluted 1:30. After incubation with the respective antisera, staining was performed by incubation with Cy2-(1:200) and Cy3-(1:600) labeled antibodies against mouse and rabbit IgG (Dianova, Hamburg, Germany). Micrographs were taken with an Olympus AX70 microscope equipped with a digital camera (color view 12,

soft imaging system SiS, Munster, Germany) and analysis software (SiS, Munster, Germany).

Specificity Controls

Method-dependent non-specificities were excluded by running controls as described (Cetin et al., (1994), *Proc. Natl. Acad. Sci. USA* 91, 2935-2939; Cetin et al., (1995) *Proc. Natl. Acad. Sci. USA* 92, 5925-5929). Antibody specificities were tested by preadsorption of the antibodies with homologous and heterologous antigenic peptides (6.25-100 mg/ml of the antiserum) (Kulaksiz et al., (2002) *Proc. Natl. Acad. Sci. USA* 99, 6796-6801; Kulaksiz et al., (2002) *Am. J. Pathol.* 161, 655-664). Preadsorption of the antibodies with homologous antigens at concentrations as low as 6.25 mg/ml completely blocked immunostaining in the liver tissues and cells, while preadsorption of the antibodies with heterologous antigens at concentrations up to 100 mg/ml had no effect on immunostaining.

Hepcidin Elisa Competitive Binding Assay

Determinations were performed in duplicate using 96-well-microtiter plates coated with goat anti-rabbit IgG (DRG Instruments GmbH, Marburg, Germany). Hepcidin antibody EG(2)-HepN, diluted 1.4000 in Tris buffered saline (TBS) containing 40 mM Tris-HCl (pH 7.3), 100 mM NaCl, was pipetted into the microtiter plates. After a 1 hour incubation at room temperature (RT), the microtiter plates were washed with TBST (TBS with 0.05% Tween 20) and 100 μ l standard samples containing various amounts of synthetic peptides or human plasma samples (58 randomized samples from our clinical laboratory) and N-terminally biotinylated hepcidin-(28-47) (Peptide Specialty Laboratories GmbH, Heidelberg, Germany) (2 ng/well) were added to each well and incubated for 1 hour at RT. The biotinylated antigen-antibody complexes were detected by streptavidin-peroxidase enzyme (Dako, Hamburg, Germany) with the substrate tetramethylbenzidine (DRG); the color reaction was stopped with 0.5 N H₂SO₄ and the extinction of the solution was read at 450/630 nm wavelength.

Expression of Hepcidin and Tfr2 in the Liver and HepG2 Cells

RT-PCR analysis demonstrated that hepcidin is highly expressed in human liver. Similarly, a 192-bp expected transcript was detected in HepG2 cells with an expression level comparable to human liver (FIG. 1). In addition, RT-PCR analyses clearly revealed that Tfr2 is highly expressed in the human liver and HepG2 cells (FIG. 1). In Western blot analysis, all hepcidin antibodies [EG(1)-HepN, EG(2)-HepN, and EG(1)-HepC] coincidentally identified an immunoreactive band of about 10 kDa in extracts of human and guinea pig liver. This liver peptide comigrated with an immunoreactive band recognized by a hepcidin antibodies in homogenates of HepG2 cells (FIG. 1). All antibodies also identified an intensively stained band at ~20 kDa in all lanes loaded with human and guinea pig liver extracts or HepG2 cell extracts. Western blot analysis of skeletal muscle extracts (control) showed neither the immunoreactive band of 10 kDa nor the strong band at 20 kDa (FIG. 1).

Western blot analysis with Tfr2 antibody BT-TFR21-S resulted in a staining of an expected (Fleming et al., (2000) *Proc. Natl. Acad. Sci. USA* 97, 2214-2219) about ~105 kDa protein in extracts of mouse liver. In extracts of human liver and HepG 2 cells, a ~95 kDa immunoreactive Tfr2 and to lesser extent a ~105 kDa immunoreactive protein was recognized by the same antibody (FIG. 1). No immunoreactivity was detected in the heart (control tissue).

Cellular and Subcellular Localization of Hepcidin and Tfr2

Immunohistochemical studies with various region-specific antibodies consistently localized hepcidin to the hepatocytes in human liver (FIG. 2). The Kupffer cells, endothelial cells, bile ducts, and the vascular system completely lacked hepcidin immunoreactivity. The same antibodies detected a strong hepcidin-immunoreactivity also in guinea pig liver (FIG. 2). Interestingly, hepatic lobule, were heterogeneous with respect to a hepcidin immunoreactivity; within a hepatic lobule, a hepcidin immunoreactive cells were predominantly located in periportal zones, and the frequency of hepcidin-positive cells continuously decreased from the portal triads toward the central veins (FIG. 3). Notably, distinct intercellular differences exist between a hepcidin positive cells; while most hepatocytes were strongly positive for hepcidin, others displayed only a faint staining or were totally unreactive for hepcidin (FIG. 3).

At the subcellular level, hepcidin immunoreactivity was confined to the basolateral (=sinusoidal) membrane domain of hepatocytes; no immunoreactivity was found at the apical membrane domain of the respective cells (FIG. 2). Similarly, immunofluorescence analysis demonstrated a strong immunoreactivity for hepcidin at the basolateral membrane domain; immunoreactivity was absent from the apical membrane domain as revealed by double staining with the C219 antibody raised against canalicular P-glycoproteins (Rost et al., (1999) *Hepatology* 29, 814-821).

Corresponding to the localization of hepcidin, protein-specific antibody BT-TFR21-S detected Tfr2 in human and mouse liver. At the cellular level, Tfr2 was found at the basolateral membrane of hepatocytes, which revealed distinct intercellular differences concerning the intensity of immunoreactivity (FIG. 4). Heterogeneity was also observed within a hepatic lobule with increasing immunoreactivity from the central veins to the portal triads.

Immunofluorescence 1N HepG2 Cells

The existence of hepcidin peptide in HepG2 cells was verified by immunocytochemistry using the corresponding peptide-specific antibodies. All antibodies identified hepcidin by the immunofluorescence technique in HepG2 cells resulting in a granular immunoreactivity pattern (FIG. 5). Coincident with the cellular localization of hepcidin, the Tfr2 antibody detected Tfr2 in the same cells (FIG. 5).

Detection of Hepcidin Propeptide in Human Plasma

Although the C-terminal antibody EG(1)-HepC revealed specific results in dot blot, Western blot, immunohistochemistry and immunofluorescence experiments (FIGS. 1-5), it did not work in ELISA. The compact folding pattern of hepcidin and its tertiary structure in the blood may account for the inability of the EG(1)-HepC antibody to identify circulating hepcidin. A sensitive hepcidin ELISA assay with a detection limit of 0.1 ng/well of the synthetic peptide was developed with the specific N-terminal hepcidin antibody EG(2)-HepN (FIG. 6). ELISA analyses with this antibody revealed a high concentration of hepcidin in the range from 5.0 to 308.3 ng per ml human plasma (n=58) (mean.±.SE; 121.2±73.4 ng/ml). No cross-reactivity was observed when heterologous peptides were used. As seen in FIG. 6, the ELISA revealed the highest resolving power between 1 and 400 ng/ml, a range, where hepcidin concentrations in human plasma were determined.

In the present invention, RT-PCR analyses with specific primers confirmed that hepcidin is highly expressed in the human liver. Three different antibodies recognizing different epitopes in a hepcidin precursor molecule concurrently identified an immunoreactive peptide of about 0.10 kDa by West-

ern blot analysis in liver extracts of two species, man and guinea pig. The apparent molecular mass of this immunoreactive peptide is in accordance with the molecular mass deduced for a hepcidin preprohormone from the cDNA sequence (Pigeon et al., (2001) *J. Biol. Chem.* 276, 7811-7819). Interestingly, a second immunoreactive band of approximately 20 kDa was detected by all hepcidin antibodies in extracts of the human and guinea pig liver but was lacking in the control tissue. This immunoreactive protein may represent a hepcidin-related peptide of higher molecular mass or, because of the twofold higher molecular mass of the second peptide, it may reflect a dimeric type of hepcidin. In fact, in a previous study an aggregation property and a possible formation of multimers was described for hepcidin-25 but not for hepcidin-20 (Hunter et al., (2002) *J. Biol. Chem.*, M205305200).

Immunohistochemical and immunofluorescence investigations with three different hepcidin antibodies revealed that, in human and guinea pig liver, hepcidin is specifically localized in hepatocytes mainly located around the portal triads; the coincident staining by different region-specific antibodies not only in the human and guinea pig liver, but also in the HepG2 cells (see below) points to hepatocytes being the source of hepcidin. Hepcidin immunoreactivity decreased from the periportal zones towards the central veins. This zonation within the portal lobules may have a functional significance, since the periportal hepatocytes have first-pass access to portal veins bringing iron-rich blood from the gut. Notably, distinct intercellular differences exist between hepcidin-positive cells even of the same liver acinus with respect to the density of hepcidin immunoreactivity that may reflect intercellular differences in expression or secretion of hepcidin.

At the subcellular level, hepcidin was concentrated at the basolateral pole of hepatocytes. No immunoreactivity was found at the apical membrane domain. The discrete distribution pattern of hepcidin at the subcellular level may infer a basolaterally directed release of hepcidin into the liver sinusoids. This directional secretion route is additionally substantiated by the detection of hepcidin prohormone in human plasma (see below); consequently, these findings provide further evidence that hepatocytes may regulate iron metabolism in an endocrine fashion via the secretion of the peptide hormone hepcidin.

To analyze the expression and cellular distribution of Tfr2 as well as the respective target membrane domains, RT-PCR, Western blot and immunohistochemical studies at the cellular level were performed. As shown in previous studies RT-PCR analyses revealed that Tfr2 is highly expressed in human liver. (Fleming et al., (2000) *Proc. Natl. Acad. Sci. USA* 97, 2214-2219). The presence of this protein was confirmed by Western blot studies using BT-TFR21-S antibody specific to human and mouse Tfr2. A ~105 kDa immunoreactive protein was detected in mouse liver extracts; this molecular mass of immunoreactive Tfr2 is slightly larger than the expected 95 kDa (Fleming et al., (2000) *Proc. Natl. Acad. Sci. USA* 97, 2214-2219) and may represent some posttranslational modifications as described previously (Kawabata et al., (2000) *J. Biol. Chem.* 275, 16618-16625). Under identical conditions, however, the Tfr2-antibody identified the protein at the expected 95 kDa molecular mass and with a lower affinity the 105 kDa protein in human liver extracts. The discrepancy between the immunoblots of human and mouse liver may be due to interspecies differences.

Immunohistochemical investigations revealed that Tfr2 is localized to hepatocytes of human and mouse liver; coincident with the cellular distribution of hepcidin, the protein-

specific antibody localized TfR2 exclusively at the basolateral membrane. This type of membrane-specific association of TfR2 argues particularly for a basolateral activation of TfR2, which is involved in iron metabolism by binding defer-
 ric transferrin and mediating uptake of transferrin-bound iron from the blood into hepatocytes (Philpott, C. C. (2002) Hepa-
 tology 35, 993-1001; Subramaniam et al., (2002) Cell Bio-
 chem. Biophys. 36, 235-239). Notably, a similar lobular
 zonation as described for hepcidin was observed for TfR2
 with decreasing immunoreactivity from the periportal zones
 toward the central veins.

Since an interaction between hepcidin and TfR2 at the
 cellular level has been discussed in previous studies (Nicolas
 et al., (2001) Proc. Natl. Acad. Sci. USA 98, 8780-8785;
 Frazer et al., (2002) Gastroenterology 123, 835-844), the
 coexistence of hepcidin and TfR2 in HepG2 cells—a well-
 differentiated hepatocellular carcinoma cell line (Aden et al.,
 (1979) Nature 282, 615-616) was analyzed, demonstrating
 in many aspects the physiology of normal hepatocytes. RT-PCR
 studies using the appropriate primer specifications and com-
 binations successfully employed in the human liver identified
 expression of hepcidin and TfR2 in HepG2 cells. At the
 translational level, the presence of hepcidin and TfR2 in
 HepG2 cells was confirmed by Western blot studies that
 yielded immunoreactive protein bands of correct molecular
 weights, comigrating with the corresponding immunoreac-
 tive bands from the liver tissues. The co-localization of the
 respective proteins in HepG2 cells was particularly substan-
 tiated by immunocytochemistry using the corresponding
 region and molecular domain-specific antibodies. All anti-
 bodies demonstrated hepcidin-labeling in HepG2 cells,
 revealing a granular immunoreactivity pattern in these cells
 that infers localization of the peptide to small secretory
 vesicles, already demonstrated in hepatocytes by electron
 microscopy (Schwartz et al., (1985) EMBO J. 4, 899-904).
 TfR2 was immunocytochemically localized, with a peculiar
 distribution pattern, to HepG2 cells.

On the basis of present data at the transcriptional and
 translational level, hepcidin and TfR2 are coexpressed in the
 liver and colocalized at the basolateral membrane domain of
 hepatocytes. In addition to a coincident localization of TfR2
 and hepcidin at the cellular level, a similar distribution of
 these molecules within the hepatic lobules with a concen-
 trated immunoreactivity in periportal zones and a decreasing
 straining toward the central veins was also detected. The
 coordinate expression of these proteins in a common (baso-
 lateral) membrane domain and their similar lobular zonation
 argue for a morphofunctional coupling of the regulating pep-
 tide hormone hepcidin and the transferrin-bound iron uptake
 via TfR2. Indeed, different data substantiate the interaction
 between hepcidin and TfR2. First, alterations in transferrin
 saturation, probably sensed by TfR2, modulate the expres-
 sion of hepatic hepcidin (Philpott, C. C. (2002) Hepatology
 35, 993-1001). Second, as revealed from quantitative RT-
 PCR analyses on human liver, hepatic expression of TfR2
 correlates significantly with hepcidin expression regulated by
 the transferrin saturation (S. G. Gehrke, H. Kulaksiz et al.
 unpublished data). Third, hepcidin and TfR2 are colocalized
 at a common cell membrane domain and reveal the same
 lobular distribution with a strong immunoreactivity in peri-
 portal zones, the site, where in case of mutations that abrogate
 expression of TfR2 (Fleming et al., (2002) Proc. Natl. Acad.
 Sci. USA 99, 10653-10658) and hepcidin (Nicolas et al.,
 (2001) Proc. Natl. Acad. Sci. USA 98, 8780-8785) but also
 hepcidin (Zhou et al., (1998) Proc. Natl. Acad. Sci. USA 95,
 2492-2497; Levy et al., (1999) Blood 94, 9-11) and B2m
 (Santos et al., (1996) J. Exp. Med. 184, 1975-1985) hepatic

iron overloading occurs. The clinical consequences of iron
 overload include cirrhosis of the liver and hepatocellular can-
 cer, diabetes, heart failure, arthritis, and hypogonadism. Zhou
 et al., Proc. Natl. Acad. Sci., 95, 2492-2497 (1998). Fourth,
 mutations in the TfR2 gene were reported to lead to hemo-
 chromatosis (Camasehella et al., (2000) Nat. Genet. 25,
 14-15); this may result from decreased hepcidin expression,
 which, in turn, results in increased iron absorption (Nicolas
 et al., (2001) Proc. Natl. Acad. Sci. USA 98, 8780-8785).
 Increased iron absorption in patients suffering from heredi-
 tary hemochromatosis leads to accumulation of iron, with
 eventual tissue damage and organ disfunction. When the dis-
 order remains untreated, premature mortality resulting from
 hepatocellular carcinoma, cirrhosis, cardiomyopathy, or dia-
 betes mellitus is common. Santos et al., (1996) J. Exp. Med.
 184, 1975-1985.

Since blood-forming tissues and sites of iron storage, such
 as the liver, are thought to transmit signals to the intestinal
 cells that indicate the body's requirements for dietary iron
 (Philpott, C. C. (2002) Hepatology 35, 993-1001), hepcidin is
 a candidate signaling factor secreted from the liver and regu-
 lating the intestinal iron absorption. However, there is still
 controversy about the existence of certain molecular forms of
 hepcidin in the blood (Krause et al., (2000) FEBS Lett. 480,
 147-150; Park et al., (2001) J. Biol. Chem. 276, 7806-7810;
 Hunter et al., (2002) J. Biol. Chem., M205305200). To ana-
 lyze whether the prohormone of hepcidin is secreted into the
 blood, and to assess the range of hepcidin concentration in
 human plasma, an ELISA was developed by applying the
 same N-terminal antibody against hepcidin prohormone used
 successfully in Western blot, immunocytochemical and
 immunofluorescence experiments. The ELISA was charac-
 terized by a high sensitivity with a detection limit of 0.1
 ng/well and a powerful resolution in the range of 1 to 400
 ng/ml; the range, where hepcidin concentrations were deter-
 mined. In the human plasma samples tested (n=58), a high
 concentration of pro-hepcidin (mean±SE 121.2±73.4
 ng/ml) was measured, ranging from 5.0 to 308.3 ng/ml, which
 is comparable with the concentration of known regulating
 peptide hormones and approximately 1.2-fold higher than the
 concentration of hepcidin in human urine (Park, C. H., Valore,
 E. V., Waring, A. J. & Ganz, T. (2001) J. Biol. Chem. 276,
 7806-7810). Interestingly, the measured concentrations
 exhibit a wide range of pro-hepcidin indicating that the pep-
 tide may be subject to strong regulation. Future experiments
 are intended to determine hepcidin concentrations in plasma
 of various subjects with disturbances of iron metabolism and
 to analyze the molecular mechanism of hepcidin regulation
 using the established ELISA.

The cDNA structure suggests that hepcidin is translated as
 an 84 amino acid prepropeptide that is N-terminally pro-
 cessed to a 20-25 amino acid peptide (id.). Although a strong
 consensus sequence for a signal sequence cleavage site is
 located between Gly24 and Ser.sup.25 that would result in a
 60 residue propeptide, previous studies failed to isolate the
 larger propeptide from native sources like liver tissue and
 blood (Id.). In addition to technical difficulties, the abundance
 of propeptide convertases in the liver may inhibit the isolation
 of certain propeptides. In this context, recent studies have
 shown that the human circulating form of hepcidin described
 by two research groups in blood (Krause et al., (2000) FEBS
 Lett. 480, 147-150) and in urine (Park et al., (2001) J. Biol.
 Chem. 276, 7806-7810), consists of the C-terminal 20-25
 amino acids of the protein. However, the ELISA measure-
 ments of the present invention were performed with the spe-
 cific-antibody raised against the N-terminus of hepcidin pre-

cursor, implying that besides the 20-25 amino acid processed forms, a hepcidin prohormone is secreted and circulates in human blood.

To understand the role of hepcidin, the knowledge about the cellular origin and the signaling pathway of the peptide is necessary. In this respect, the present invention describes hepcidin immunoreactivity in human and guinea pig liver, where it is localized to the basolateral membrane domain of hepatocytes. Previous studies have speculated on a possible connection between these cells and the absorptive enterocytes (Hunter et al., (2002) J. Biol. Chem., M205305200; Anderson et al., (2002) Biochem. Soc. Trans. 30, 724-726). The present invention describes the detection of pro-hepcidin in the human plasma thereby indicating that hepatocytes secrete the prohormone of hepcidin that may decrease dietary iron absorption via an endocrine pathway. Moreover, hepcidin was detected in HepG2 cells, where the newly discovered transferrin receptor type 2 was also found. The simultaneous existence of hepcidin and TfR2 in HepG2 cells and their common polarized localization and lobular distribution in the liver may indicate that hepcidin is an intrinsic hepatic peptide morphofunctionally coupled to TfR2, which is regulated by transferrin saturation and, in turn, modulates expression of hepcidin. Hence, pertinent findings are expected from studies on the signaling pathway of hepcidin.

Enzyme Immunoassay for the Quantitative Measurement of Hepcidin in Human or Animal Serum and Other Body Fluids.

In one embodiment of the invention a Hepcidin enzyme immunoassay ("EIA") is used. An EIA is a solid phase enzyme-linked immunosorbent assay (ELISA) based on the competitive principle. Microtiter wells of a 96 well microtiter plate are coated with a polyclonal rabbit anti-hepcidin antibody. An unknown amount of Hepcidin present in the sample and a fixed amount of Hepcidin conjugated with a biotin molecule compete for the binding sites of the Hepcidin antibodies immobilized on the wells. After one hour incubation the microtiter plate is washed to stop the competition reaction. In the following incubation the bound biotin molecules are detected with streptavidin horseradish peroxidase. After one half hour of incubation the plate is washed a second time. Having added the substrate solution the concentration of Hepcidin is inversely proportional to the optical density measured.

Materials

1. Microtiter wells, wells coated with Anti-Hepcidin antibody (96 wells).
2. Reagent: Biotin Conjugate (Hepcidin conjugated to biotin) 7 ml.
3. Reference Standard Set, 1.0 ml each 0, 20, 100, 500, 1000 ng/ml.
4. Reagent: Enzyme Complex (Streptavidin conjugated to horseradish peroxidase ("HRP")) 14 ml.
5. Reagent: Substrate Solution-HS-TMB, 14 ml.
6. Stop Solution, 0.5M H₂SO₄, 14 ml.
7. Wash Solution, 40x, 30 ml.
8. A microtiterplate reader (450±10 nm) (e.g., the DRG Instruments Microtiterplate Reader).
9. Precision micropipettes with disposable tips for 50 and 100 µl.
10. Standard refrigerator.
11. Absorbent paper.
12. Deionized water.

While this embodiment has been described in terms of preferred materials, a person skilled in the art of the invention will appreciate that other materials can be used in the invention. For example, one of skill in the art will appreciate that

complementary binding moieties other than biotin/streptavidin, as well as enzyme/substrate combinations other than horse radish peroxidase/peroxide, may be used in the invention.

Storage Conditions

When stored at 2° to 8° C. unbroken reagents will retain reactivity until expiration date. Do not use reagents beyond this date. Microtiter wells must be stored at 2° to 8° C. Once the foilbag has been broken care should be taken to close it tightly again. The immuno-reactivity of the coated microtiter wells is stable for approximately 6 weeks in the broken, but tightly closed plastic zip pouch containing the desiccant.

Specimen Collection and Preparation

Human or animal serum or EDTA plasma should be used in the assay. No special pretreatment of the biological sample is necessary. The biological sample may be stored at 2-8° C. for up to 24 hours, and should be frozen at -20° C. or lower for longer periods. Do not use grossly hemolyzed or grossly lipemic specimens. For other sample material a special extraction protocol may be necessary.

Performance of the Assay

General Remarks:

1. All reagents and specimens must be allowed to come to room temperature before use. All reagents must be mixed without foaming.
2. Once the test has been started, all steps should be completed without interruption.
3. Use new disposable plastic pipette tips for each reagent, standard or specimen in order to avoid cross contamination. For the dispensing of the Substrate Solution and the Stop Solution avoid pipettes with metal parts.
4. Pipette standards and samples onto the bottom of the well. For pipetting of Enzyme Conjugate and Stop Solution it is recommended to hold the pipette in a vertical position above the well and dispense the correspondent solution into the center of the well so that a complete mixing of Enzyme Conjugate with sample or standard and of the Stop Solution with the Substrate Solution is achieved.
5. Before starting the assay, it is recommended that all reagents be ready, caps removed, all needed wells secured in holder, etc. This will ensure equal elapsed time for each pipetting step without interruption.
6. As a general rule the enzymatic reaction is linearly proportional to time and temperature. This makes interpolation possible for fixed physico-chemical conditions. If in a test run the absorbance of Zero Standard is lower than 1,0 or above the upper performance limit of your microtiterplate spectrophotometer you can extend or reduce the incubation time of the final enzymatic formation of color to 30 or 10 minutes accordingly. Since calibrators are assayed in each run, absorbance fluctuations do not affect the result.
7. The Substrate Solution should be colorless or slightly blue or green. If the solution is dark blue the reagent is unusable and must be discarded.
8. During incubation with Substrate Solution avoid direct sunlight on the microtiter plate.

Reagent Preparation

Wash Solution: Add deionized water to the 40x concentrated Wash Solution (contents: 30 ml) to a final volume of 1200 ml. The diluted Wash Solution is stable for 2 weeks at room temperature.

Assay Procedure

1. Secure the desired number of coated strips in the holder.
2. Dispense 50 µl of Hepcidin Standards into appropriate wells.

29

3. Dispense 50 μ l of sample into selected wells.
4. Dispense 50 μ l of Biotin Conjugate into each well.
5. Thoroughly mix the plate for 10 seconds. It is important to have complete mixing in this step.
6. Incubate for 60 minutes at room temperature.
7. Briskly shake out the contents of the wells.
8. Rinse the wells 3 times with diluted Wash Solution (400 μ l per well). Strike the wells sharply on absorbent paper to remove residual droplets.
9. Add 100 μ l Streptavidin HRP Complex to all wells.
10. Incubate for 30 minutes at room temperature.
11. Briskly shake out the contents of the wells.
12. Rinse the wells 3 times with diluted Wash Solution (400 μ l per well). Strike the wells sharply on absorbent paper to remove residual droplets.
13. Add 100 μ l of Substrate Solution to each well, at timed intervals.
14. Incubate for 15 minutes at room temperature.
15. Stop the enzymatic reaction by adding 100 μ l of Stop Solution to each well at the same timed intervals as in step 10 and determine the absorbance of each well at 450 ± 10 nm.

Final Reaction Stability

It is recommended that the wells be read within 30 minutes following step 15.

Calculation of Results

Any microwell reader capable of determining the absorbance at 450 ± 10 nm may be used. The Testosterone value of each sample is obtained as follows:

1. Using linear-linear or semi log graph paper, construct an standard curve by plotting the average absorbance (Y) of

30

each Reference Standard against its corresponding concentration (X) in ng/ml. For construction of the standard curve we recommend a four parameter logistic function.

2. Use the average absorbance of each sample to determine the corresponding Testosterone value by simple interpolation from this standard curve, multiplying by the initial sample dilution, if necessary.

A DRG ELIZA MAT 3000 and the DRG Regression Program allow the reading and computer assisted interpretation using a four parameter logistic function.

INDUSTRIAL APPLICABILITY

The invention has applications in connection with diagnosing a disease condition characterized by non-physiological levels of hepcidin protein, including prohepcidin and fragments thereof.

Although the invention herein has been described with reference to particular embodiments, it is to be understood that these embodiments are merely illustrative of the principles and applications of the present invention. It is therefore to be understood that numerous modifications may be made to the illustrative embodiments and that other arrangements may be devised without departing from the spirit and scope of the present invention as defined by the appended claims.

All patent and non-patent publications cited in this specification are indicative of the level of skill of those skilled in the art to which this invention pertains. All these publications and patent applications are herein incorporated by reference to the same extent as if each individual publication or patent application was specifically and individually indicated to be incorporated herein by reference.

20

The invention claimed is:

1. A kit for detecting a level of a hepcidin precursor, the kit comprising: an anti-hepcidin precursor antibody or fragment thereof that specifically binds to one or more epitopes of the hepcidin precursor amino acid sequence located within amino acids 25-49 of SEQ ID NO: 2, and a reagent that binds directly or indirectly to the antibody or fragment thereof, and wherein the antibody or fragment thereof detects the hepcidin precursor by Western blot analysis in a tissue or a liquid sample obtained from a subject.
2. The kit of claim 1 wherein the anti-hepcidin precursor antibody or fragment thereof is immobilized on a support.
3. The kit of claim 2 wherein the reagent comprises the hepcidin precursor complexed with a first binding molecule.
4. The kit of claim 3 wherein the first binding molecule is biotin.

10

5. The kit of claim 4 wherein the kit further comprises an enzyme complexed with a second binding molecule and a substrate of the enzyme.
6. The kit of claim 5, wherein the second binding molecule is streptavidin.
7. The kit of claim 5, wherein the enzyme is horse radish peroxidase, and the substrate comprises peroxide.
8. An isolated antibody or fragment thereof that specifically binds to one or more epitopes of a hepcidin precursor amino acid sequence located within amino acids 25-49 of SEQ. ID. NO. 2, and wherein the antibody or fragment thereof detects an amino acid sequence consisting of amino acids 25-84 of SEQ ID NO: 2 by Western blot analysis in a tissue or a liquid sample obtained from a patient.
